

# Intelligent Control Approaches for UAVs

K. KrishnaKumar

NeuroEngineering Laboratory  
NASA Ames Research Center

Presented at UAV-MMNT03

# Presentation Outline

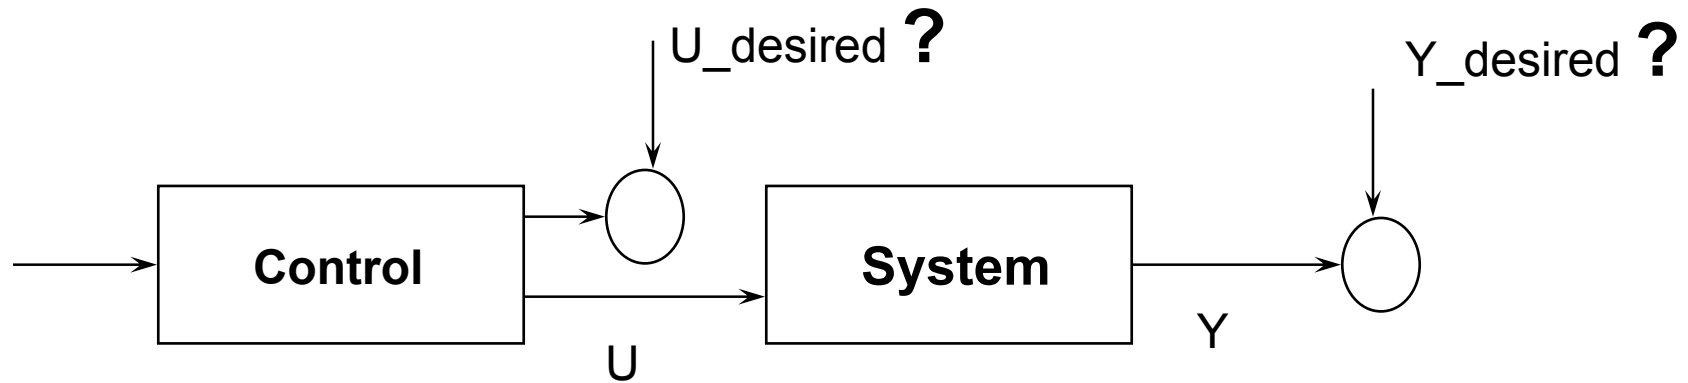

- Intelligent Control Background
- Intelligent Flight Control Research @  
NASA Ames

- **Intelligent Control Background**
  - What are intelligent systems
  - What is intelligent control
  - Intelligent control architectures

# Defining Intelligent Systems

- An Intelligent System is one that exhibits any of the following traits:
  - ✓ Learning
  - ✓ Adaptability
  - ✓ Robustness across problem domains
  - ✓ Improving efficiency (over time and/or space)
  - ✓ Information compression (data to knowledge)
  - ✓ Extrapolated reasoning

*IS is seen as Rationalistic AI: Intelligence for doing the right thing*

Two Error Signals are needed:

1. System Performance Error Signal
2. Control Error Signal

# Questions

How do we say that one controller is more intelligent than the other?

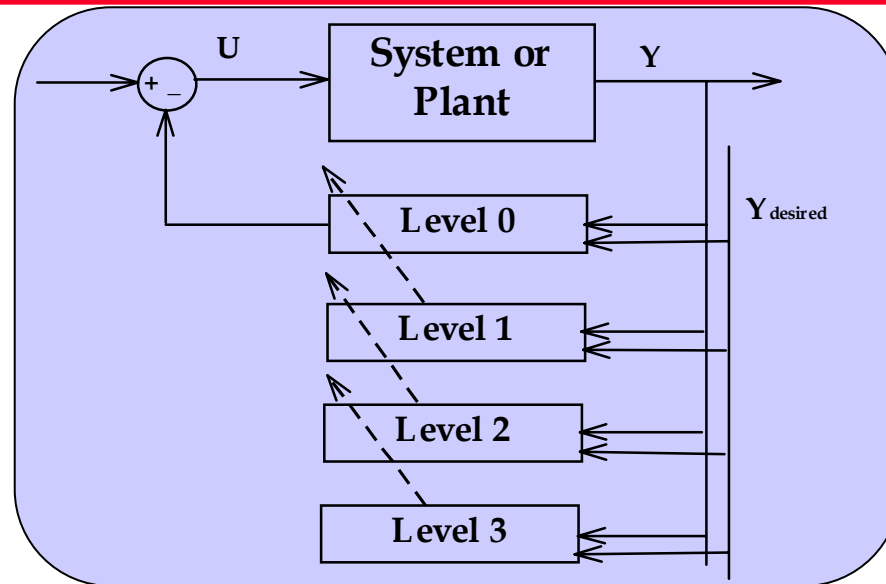

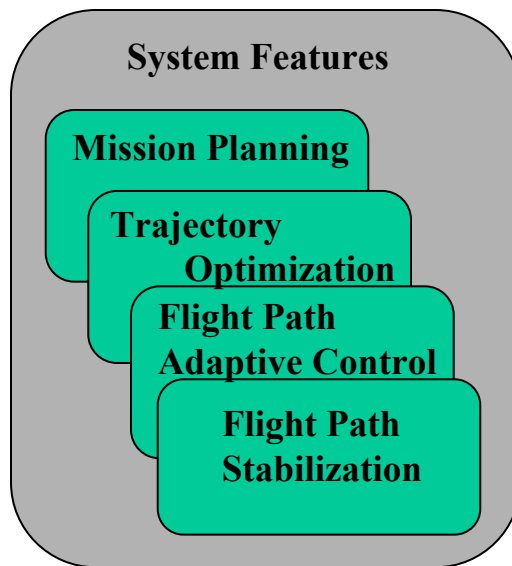

Can the intelligence be improved?

Can intelligence be measured?

---

Answer : Levels of Intelligent Control

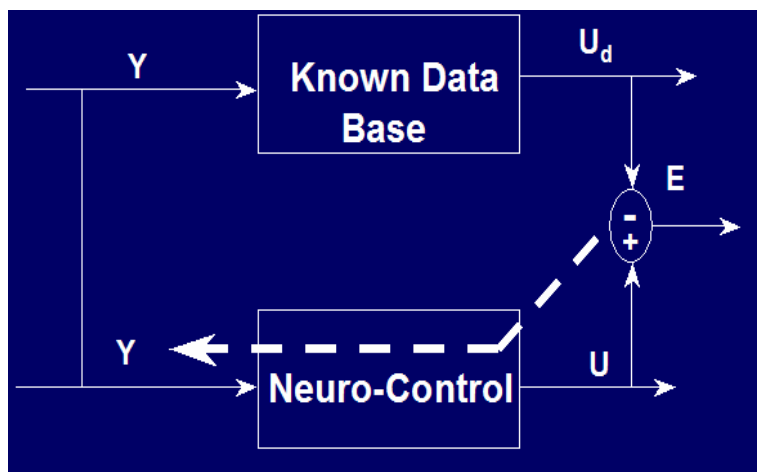

# Levels of Intelligent Control

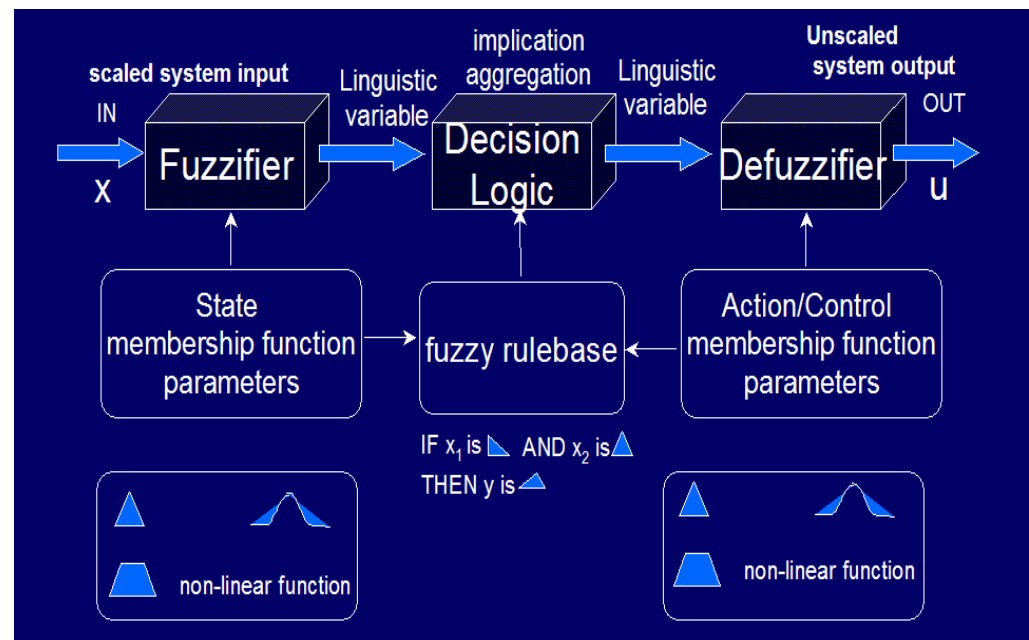

Lev	Self improvement of:	Description
0	Tracking Error (TE)	Robust Feedback control (Error tends to zero).
1	TE + Control Parameters (CP)	Robust feedback control with adaptive control parameters (error tends to zero for non-nominal operations; feedback control is self improving).
2	TE + CP + Performance Measure (PM)	Robust, adaptive feedback control that minimizes or maximizes a utility function over time (error tends to zero and a measure of performance is optimized).
3	TE+CP+PM+ Planning Function	Level 2 + the ability to plan ahead of time for uncertain situations, simulate, and model uncertainties.

## ➡ Level 0: Robust stabilization

- Gain Scheduling
- Supervised neuro-control
- Fuzzy control
- Mimic a controller
- Implicit Control

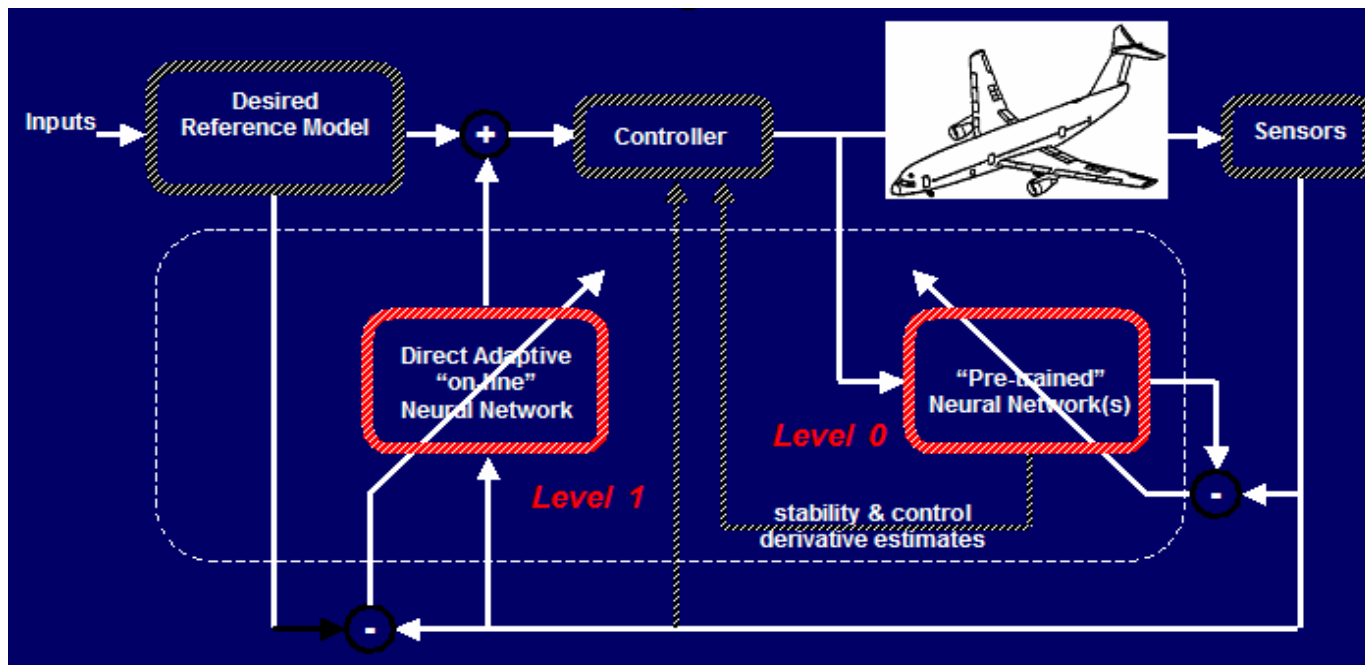

K. KrishnaKumar

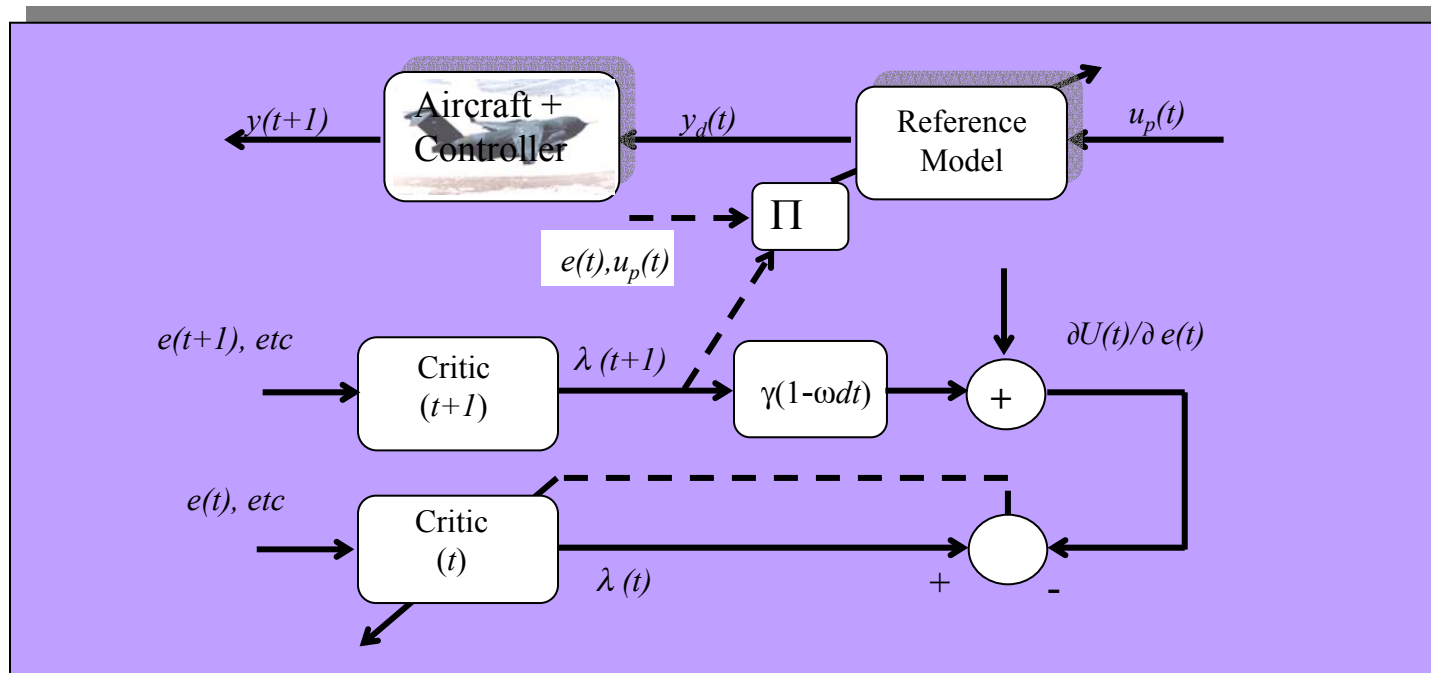

## ➡ Level 1: Adaptive Control

- **Learn Systems and Controller Parameters**
- **Neural adaptive Control**
- **Adaptive inverse Control**
- **Approximate Controller error signal**

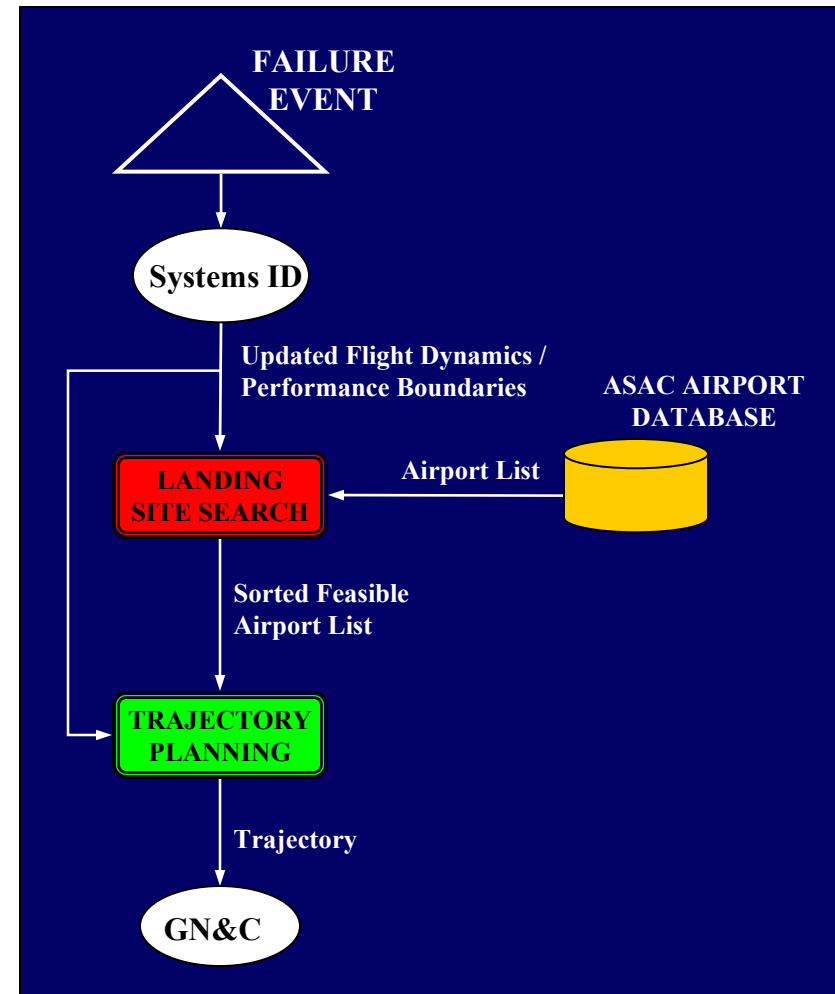

## ► Level 2: Optimal Control

- Reinforcement Learning
- Control Allocation
- Dynamic programming
- Linear Adaptive Critics
- Non-linear Adaptive Critics

## ➡ Level 3: Planning Control (More AI-like)

- Strategic Planning
- Strategic search
- Mission Planning
- HTN: hierarchical task network
- Production-based cognitive architectures
- Decision-theoretic (MMDP)
- Etc..

# NASA Ames

## Intelligent Flight Control Applications

# Manned Aircraft Objectives

Develop flight control technologies that can automatically compensate for problems or failures **when** they occur

Develop these technologies and capabilities in a **generic** sense so that they can be applied to different vehicle classes

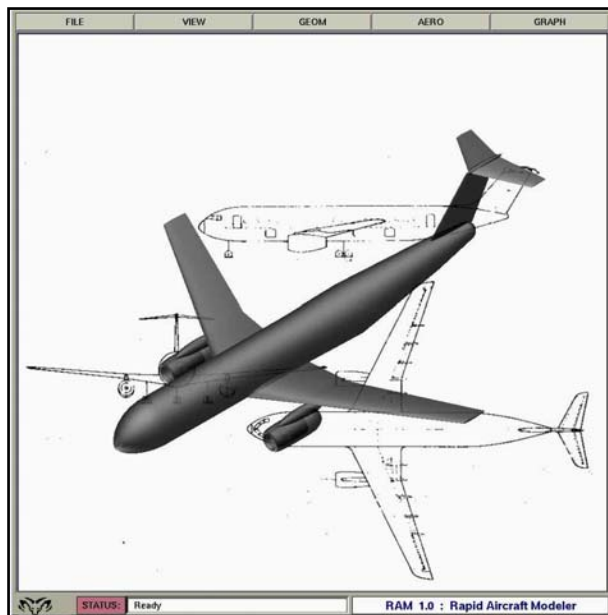

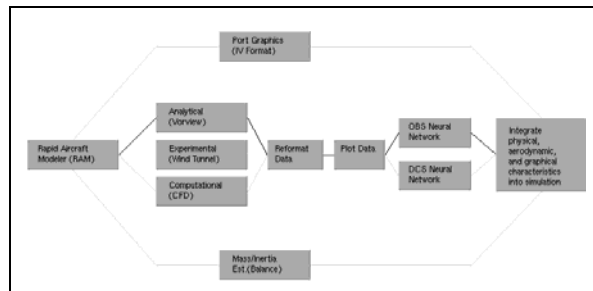

## Application Platforms

- B 757 class aircraft – Simulation only
- F-15 – In Flight test
- C-17 – Flight tests in 2004

# Pre-Trained Neural Networks

## Step 3

*Levenberg Marquardt neural net Optimal  
Pruning Algorithm*

# Neural Flight Control Architectures

# Level 1 Adaptive Control Equations

**Plant:**  $\ddot{x} = f(\dot{x}, x, \delta)$

**Linear approximation:**  $\ddot{x} \cong A\dot{x} + B\delta$

**Control law design:**  $\delta = B^{-1}(\nu - A\dot{x})$

**Closed loop:**  $\ddot{x} = f(\dot{x}, x, \delta) = \nu + \tilde{f}$

**Inversion error:**  $\tilde{f} = f - \nu = f(\dot{x}, x, \delta) - (A\dot{x} + B\delta)$

# Level 1 Control Equations

**Provide compensation for the inversion error by design of  $\mathcal{U}$**

$$\mathcal{U} = \mathcal{U}_0 - \mathcal{U}_{AD}$$

**$\mathcal{U}_0$  is designed as output of a linear controller, e.g. “PI” control.**

$$\mathcal{U}_0 = \ddot{x}_c + K_p(\dot{x}_c - \dot{x}) + K_I(x_c - x);$$

**$\mathcal{U}_{AD}$  is the adaptive control**

# Level 1 Control Equations

**Rewrite**

$$\tilde{x} = (x_C - x) \quad \text{and} \quad e = \begin{bmatrix} \tilde{x} \\ \dot{\tilde{x}} \end{bmatrix}$$

$$\text{With } a = \begin{bmatrix} 0 & 1 \\ -K_D & -K_P \end{bmatrix} \quad \text{and} \quad b = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

**We have the tracking error dynamics as:**  $\dot{e} = a e + b(v_{AD} - \tilde{f})$

**Neural Network Input Map:**

$$v_{AD} = W^T \mathcal{A}(x, V) \quad \text{for sigma-pi NN}$$

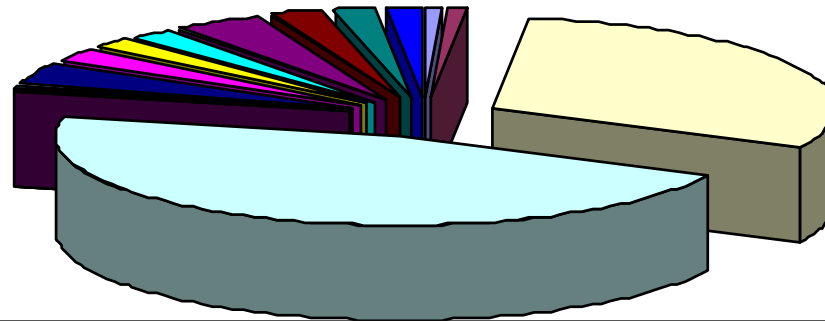

$$v_{AD} = W^T \Phi(x, V) \quad \text{for RBF NN}$$

# Level 2: Optimal Control Allocation

- When to allocate?
  - Control limit violation
  - Rate saturation
  - Control failure
- How to allocate?
  - Optimal allocation using Linear Programming
    - Conventional hierarchy
    - Best available hierarchy

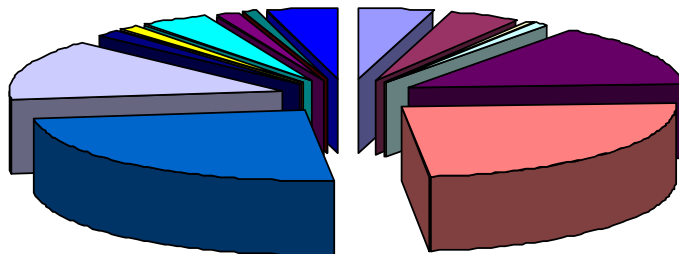

# Example Aerodynamic Control Authority

## Directional Authority

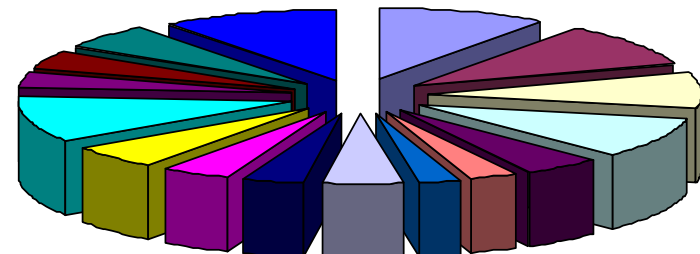

aileron_left	aileron_right	rudder_upper	rudder_lower
elevator_lob	elevator_lib	elevator_rib	elevator_rob
spoiler_lib	spoiler_lmib	spoiler_lmob	spoiler_lob
spoiler_rib	spoiler_rmib	spoiler_rmob	spoiler_rob

## Pitch Control Authority

## Roll Control Authority

Dynamic System is defined as

$$\left[ \dot{X} \right] = f(X) + [B][u] + f_{trim}$$

Let us write  $[B][u]$  as

$$\begin{bmatrix} B_{UU} & B_{UL} \\ B_{LU} & B_{LL} \end{bmatrix} \begin{bmatrix} u_U \\ u_L + \Delta u_L \end{bmatrix} = \begin{bmatrix} B_{UU} & B_{UL} \\ B_{LU} & B_{LL} \end{bmatrix} \begin{bmatrix} u_U \\ u_L \end{bmatrix} + \begin{bmatrix} B_{UU} & B_{UL} \\ B_{LU} & B_{LL} \end{bmatrix} \begin{bmatrix} 0 \\ \Delta u_L \end{bmatrix}$$

---

$u_U$  = Unlimited Control Vector from Dynamic Inverse

$u_L + \Delta u_L$  = Limited Control Vector from Dynamic Inverse

# L P Formulation (cont'd)

What we need is help  
from Unlimited Control

$$\begin{bmatrix} B_{UU} \Delta u_U \\ B_{LU} \Delta u_U \end{bmatrix} = \begin{bmatrix} B_{UL} \Delta u_L \\ B_{LL} \Delta u_L \end{bmatrix}$$

Let us now define a control reallocation matrix  $[\lambda]$  such that

$$[\Delta u_U] = [\lambda][\Delta u_L] \quad \Rightarrow \quad \begin{bmatrix} B_{UU} \\ B_{LU} \end{bmatrix} [\lambda] = \begin{bmatrix} B_{UL} \\ B_{LL} \end{bmatrix}$$

Define a linear relationship  $[\alpha][\lambda] = [\beta]$

$$[\alpha][\lambda_1 \quad \lambda_2 \quad . \quad . \quad \lambda_m] = [\beta_1 \quad \beta_2 \quad . \quad . \quad \beta_m]$$

# LP Formulation (Cont'd)

$$\min_{\lambda_i} (w_i^T \lambda_i)$$

Subject to

$$[\alpha][\lambda_i] \leq [\beta_i] \quad \text{and} \quad 0 \leq \lambda_i \leq \lambda_{\max}$$

---

Example: 4 control inputs

$$[W] = \begin{bmatrix} w_{11} & w_{12} & w_{13} & w_{14} \\ w_{21} & w_{22} & w_{23} & w_{24} \\ w_{31} & w_{32} & w_{33} & w_{34} \\ w_{41} & w_{42} & w_{43} & w_{44} \end{bmatrix} = [w_1 \quad w_2 \quad w_3 \quad w_4]$$

# Conventional & Best Hierarchies

	Elevator	Left Aileron	Right Aileron	Rudder
Elevator	<b>Primary</b>	<i>Secondary</i>	<i>Secondary</i>	
Left Aileron		<b>Primary</b>	<i>Secondary</i>	<i>Tertiary</i>
Right Aileron		<i>Secondary</i>	<b>Primary</b>	<i>Tertiary</i>
Rudder		<i>Secondary</i>	<i>Secondary</i>	<b>Primary</b>

## Conventional

$$[W]^T = \begin{bmatrix} * & 1 & 1 & 100 \\ 100 & * & 1 & 10 \\ 100 & 1 & * & 10 \\ 100 & 1 & 1 & * \end{bmatrix}$$

## Best

$$[W]^T = \begin{bmatrix} * & 1 & 1 & 100 \\ 100 & * & 1 & 1 \\ 100 & 1 & * & 1 \\ 100 & 1 & 1 & * \end{bmatrix}$$

# Implementation

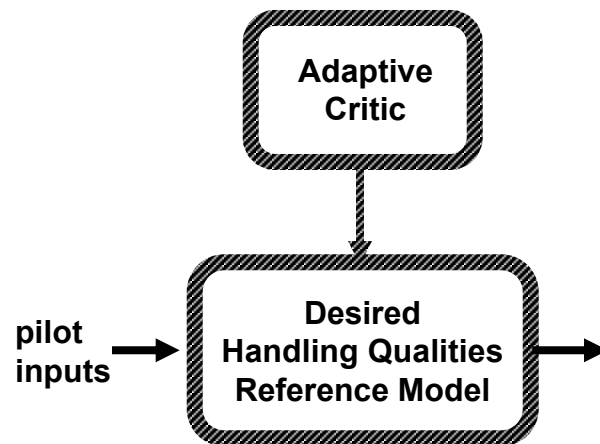

- Primary Cost based on “surface”

$$\min_u (w^T u)$$

- Auxiliary Cost based on “axis error”

$$\min_u (c^T e)$$

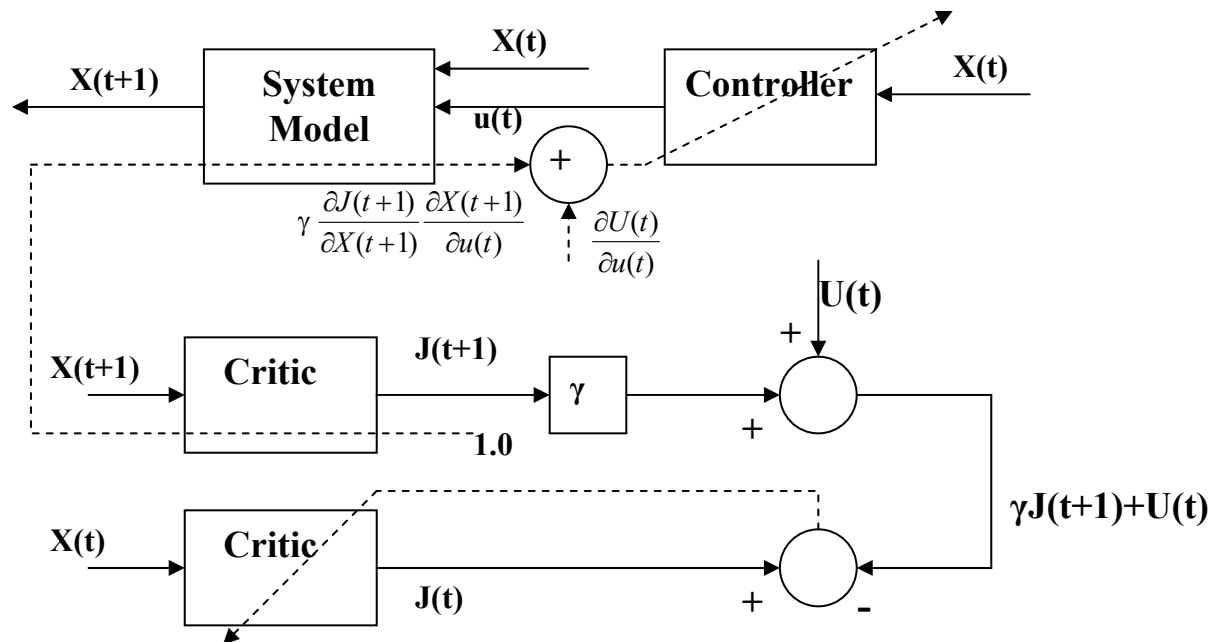

## Reference Model Adaptation using an Adaptive Critic

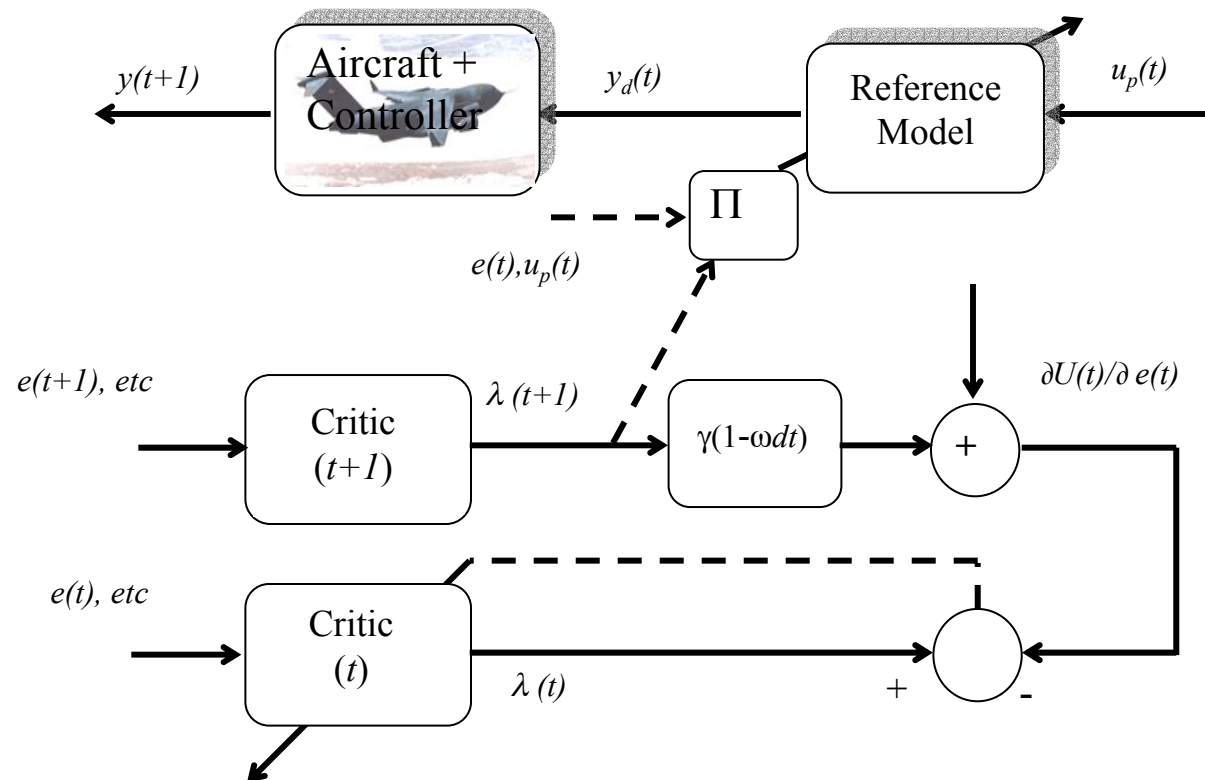

# Adaptive Critic

Adaptive critic designs have been defined as designs that attempt to approximate dynamic programming.

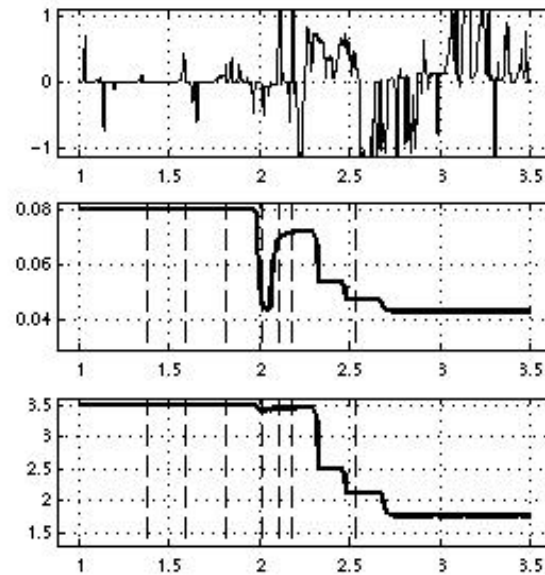

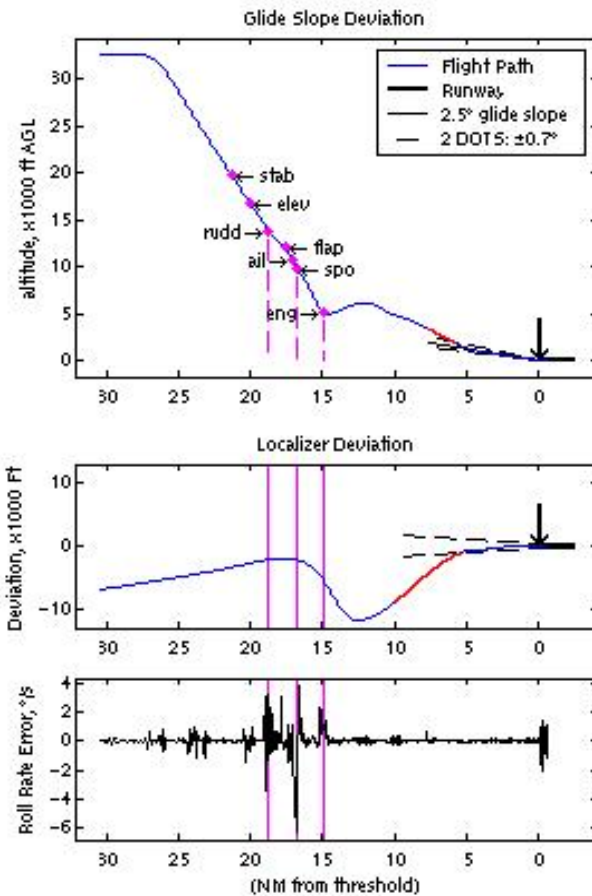

$$J(t) = \gamma J(t+1) + \min_u U(t)$$

# Level 2 Control

# Results for Series of Failures

During tactical descent (failures on one side)

- 23,000': Stab frozen at trim
- 20,000': 2 Elevators frozen at 0 deg.
- 17,000': Upper rudder hard over
- 15,000': Outboard flap fails retracted
- 14,000': Aileron frozen at 0 deg.
- 13,000': Two outboard spoilers frozen at 0 deg.

When engines come out of reverse: Outboard engine seizes

# Intelligent Maneuvering of UAVs

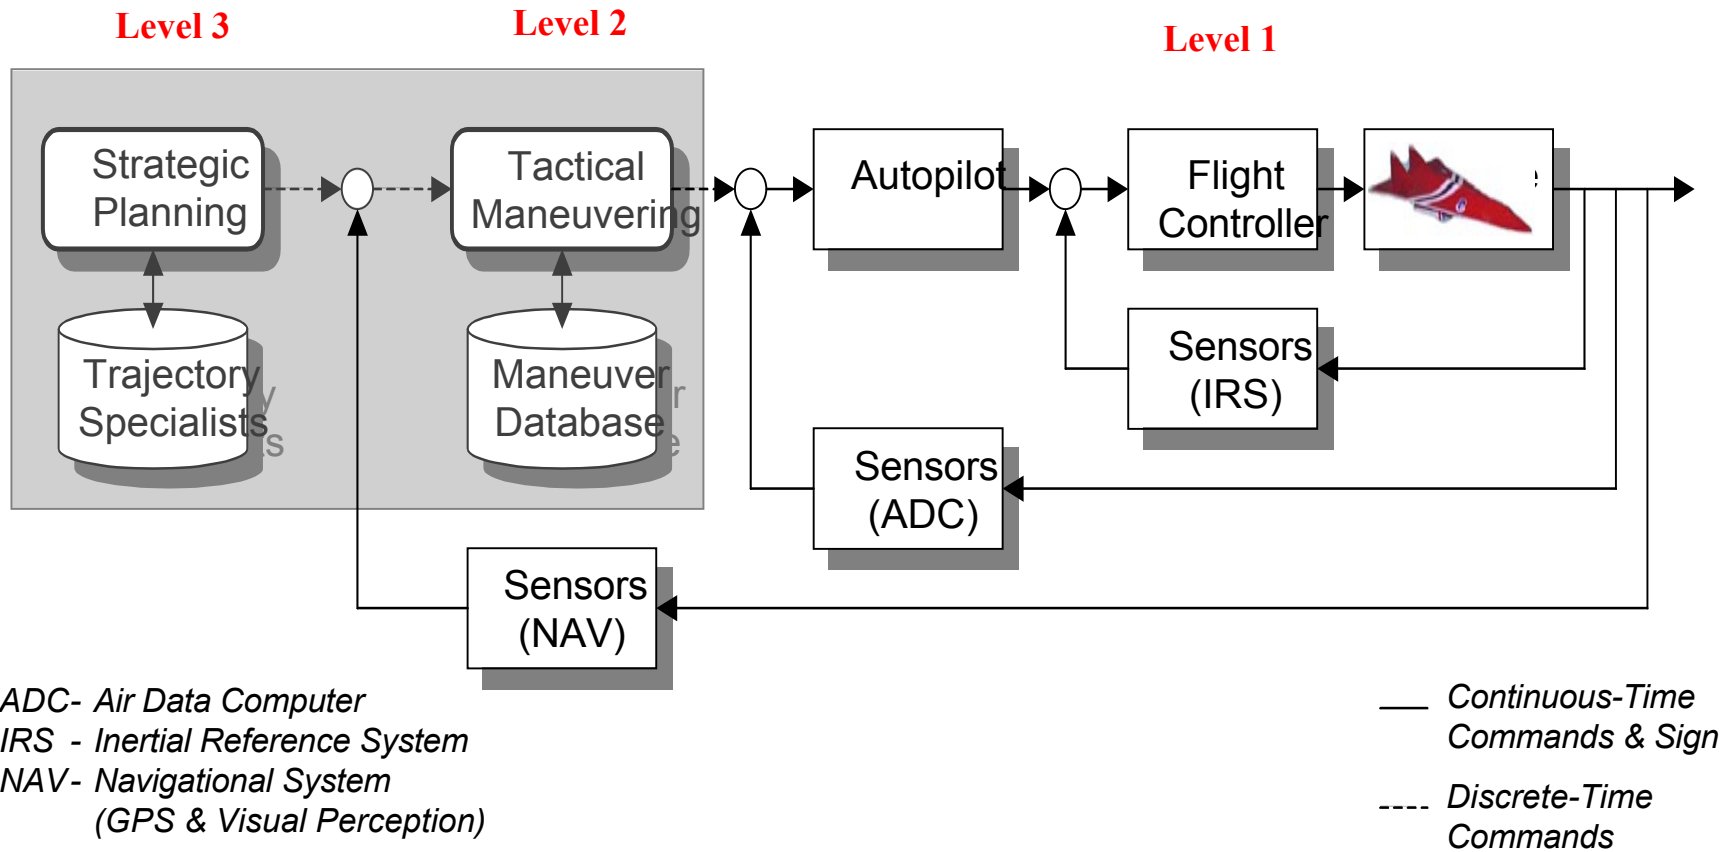

- Goals

- Provide increasingly *higher levels of automation*, capable of responding to changing goals and objectives, while taking corrective actions in the presence of internal or external events.

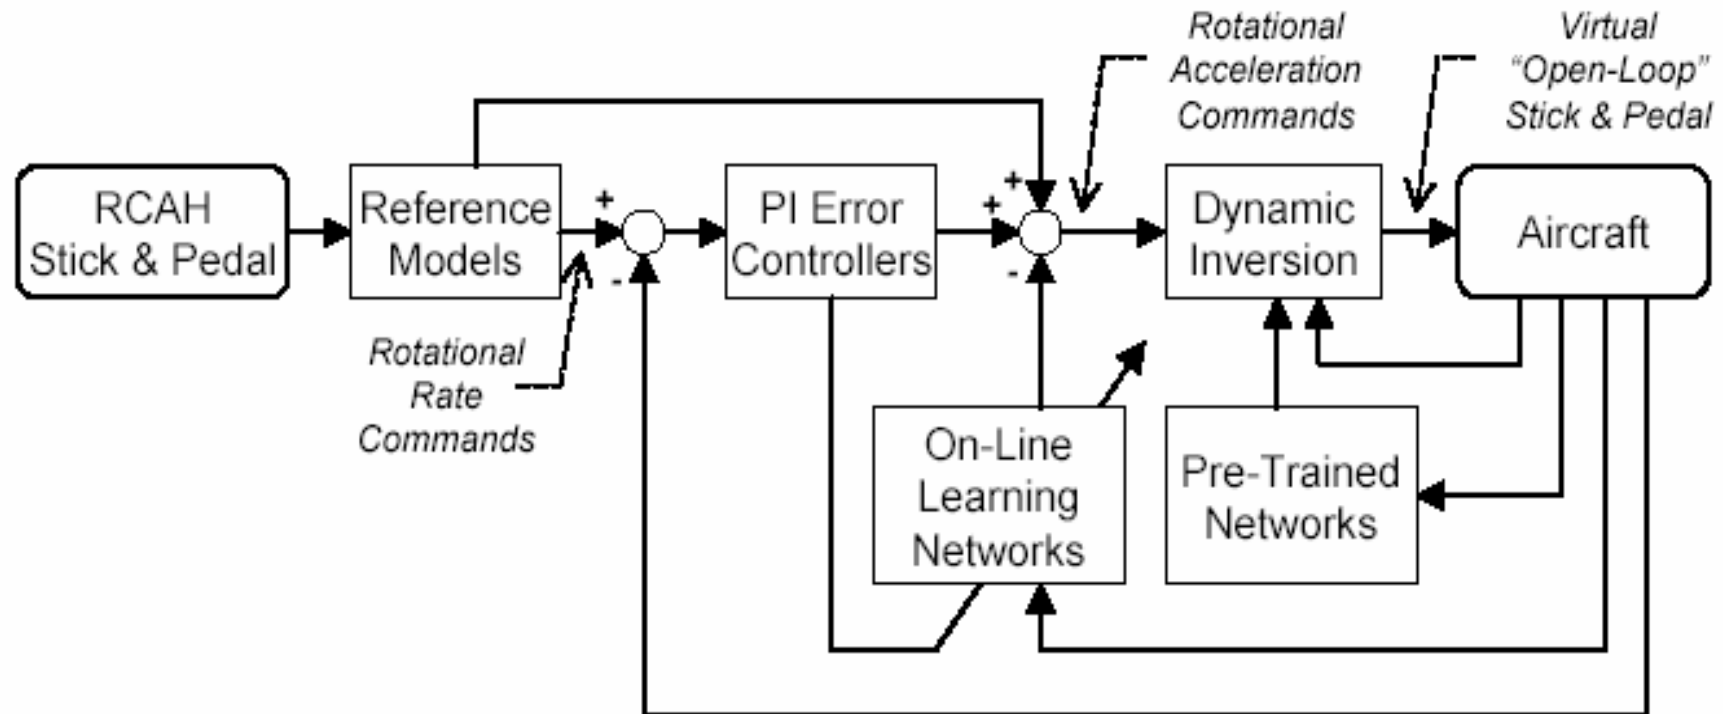

- Allow pilots, ground-based operators or **autonomous executives** to defer the responsibilities of performing and supervising tasks, to focus on *managing goals and objectives*.

# Intelligent Maneuvering of UAVs

# Flight Controller

# Tactical Maneuvering

*Performs time-critical flight path operations, which includes aggressive maneuvers in the presence of unexpected obstacles.*

## •Inputs

### –Commands

- Reference Targets / Trajectory
- Performance Parameters

### –Awareness

- Threat Detection (eg. TCAS, GCAS)
- Vehicle Performance Models

## •Outputs

### –Maneuver Sequence

- Control Law Specific Modes & Targets
- Transition Criteria

### Model Predictive Take-off and Landing

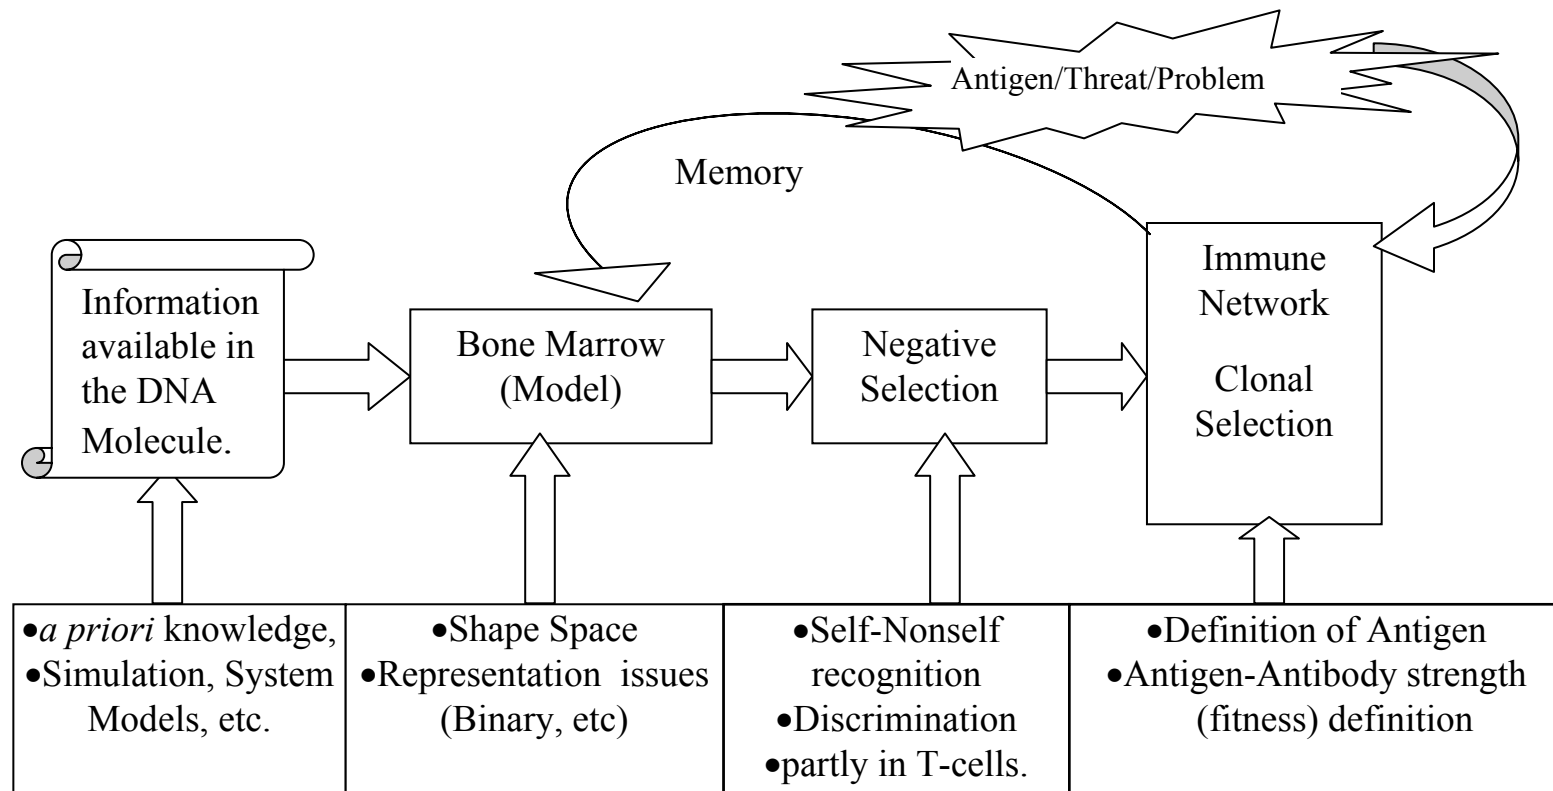

Eric Wan

NeuroEngineering Lab

# A system-level description of the Immune System Metaphor

# Tactical Maneuvering Database

*Contains general and aircraft specific maneuvering database elements, each corresponding to associated control laws. Pre-canned maneuver sequences represent domain expertise.*

## •Elements

- Control Law
  - Mode & Target Definition
- Aircraft Specific
  - Flight Envelope Validation Logic
- Specifications
  - Closed-Loop Predictive Models ( $x_0, \dots, x_f$ )
  - Resource Allocation Table (e.g. lat, lon, ped, thr/col)

## •Sequences

- Elements
  - Specified Parameters / Arguments
- Transition Criteria / Termination Logic
  - Time-Based and/or Condition-Based
- Interrupts
  - Abort Conditions & Abort Sequence

### Bank to Turn Element

Heading Select (coord. turn)

Mode: HDGSEL

Target: Heading = [arg1] deg

Envelope: IAS > 180 kts,  $|\theta| < \dots$

Model:  $\phi_o/\phi_i = \tau/(\tau s + 1)$ ,

$\phi'_{\max} = g \cos(\theta) \sin(\phi_{\max})/v_t$

RAT: LAT/PED

### Bank & Pull to Turn Sequence

Bank Left: 0

Normal Accel. (speed control)

Bank Right: +90

Mode: BANKSEL

Target: Bank = 90 deg,  $V_z = V_{z_0}$

Envelope: mach > 0.4,  $|\alpha| < \dots$

Model:  $\phi_o/\phi_i = \tau/(\tau s + 1)$ ,

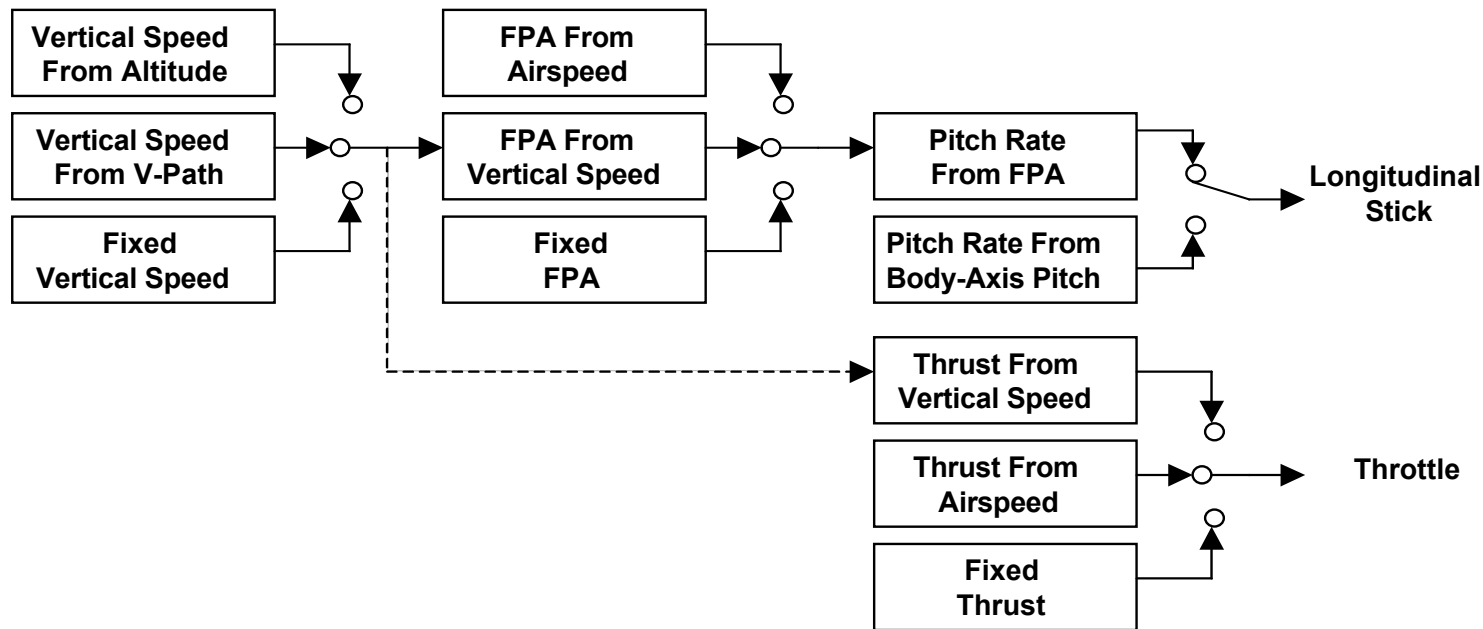

$\phi'_{\max} = p_{\max}$

$V_z = V_{z_0}$

RAT: LAT/PED

# Autopilot System (Example)

- Longitudinal Modes

- Pitch,  $N_z$ , AoA, FPA; Mach, IAS, Vertical Speed; Vertical Path, Altitude

- Thrust Modes

- Mach, IAS, Vspd, Thrust; Vertical Path, Altitude, FPA

- Lateral Modes

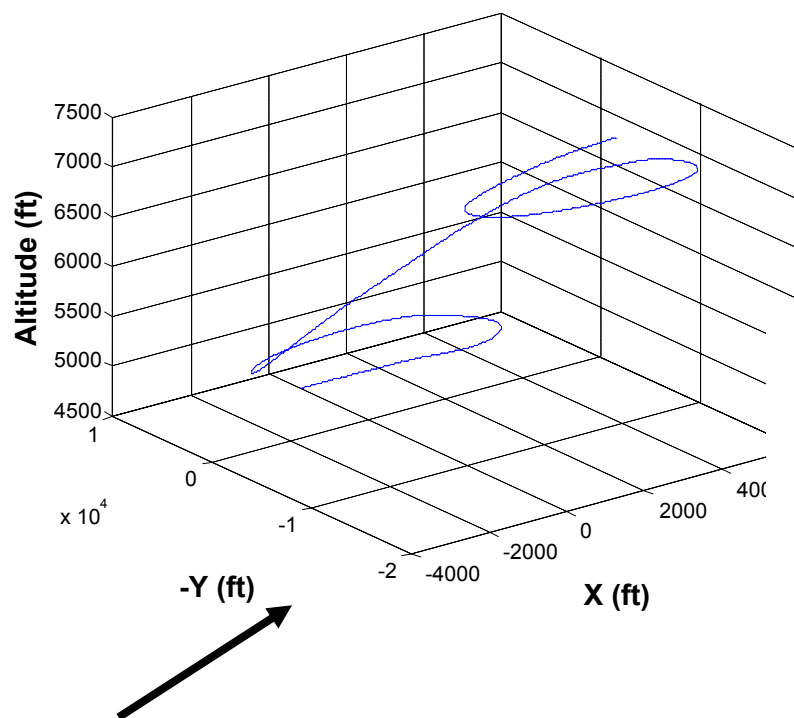

- Bank, Roll Rate; Heading, Track; Lateral Path

- Directional Modes

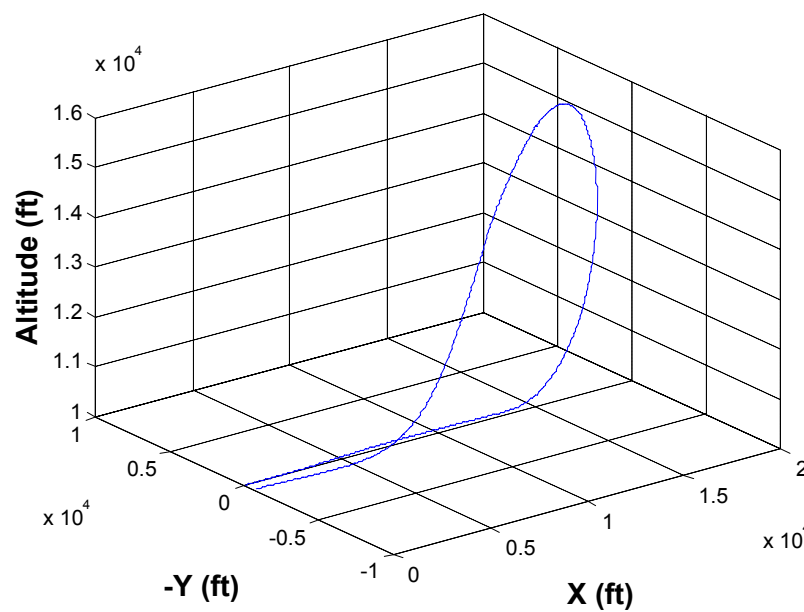

- Sideslip,  $N_y$ , Heading

# Results

Three Chained Modes →

# Strategic Maneuvering

*Performs long-term planning that meets dynamic mission goals and objectives, within mission constraints and performance limitations.*

- Inputs

- Tear Drop, Low-Altitude, Enroute

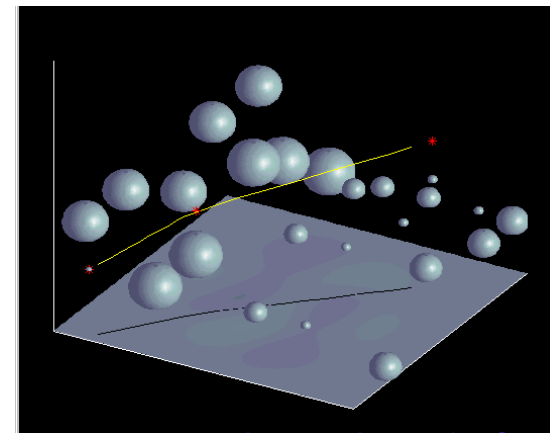

- Evolutionary Navigation

*Low-Altitude Energy Management*

*John Bull*

*Obstacle Avoiding Evolutionary Navigation*

# Optimal Way Point Computation Around Obstacles Using Evolutionary Algorithms

## ➤ The Algorithm:

- Step 1: Determine the obstacles that are in the path of the flight
- Step 2: Place the waypoints for the aircraft on the circumference of the obstacles
- Step 3: Compute the path between the start and the end using the waypoints.
- Step 4: Compute a fitness function
- Step 5. After “n” iterations the best set of waypoints defines the navigation path.

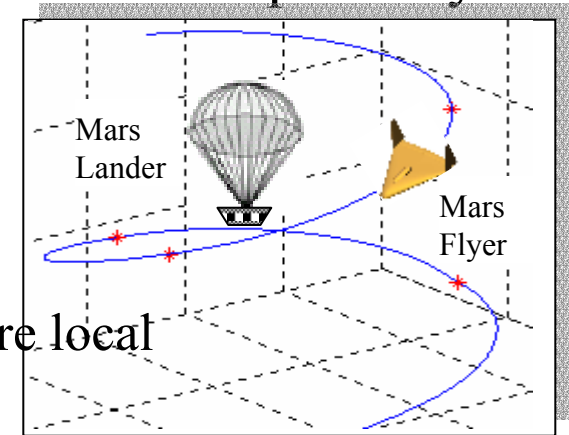

# Demo

Exploration of Mars using Free-flyers with sensors inspired by Nature

## Controller Objectives:

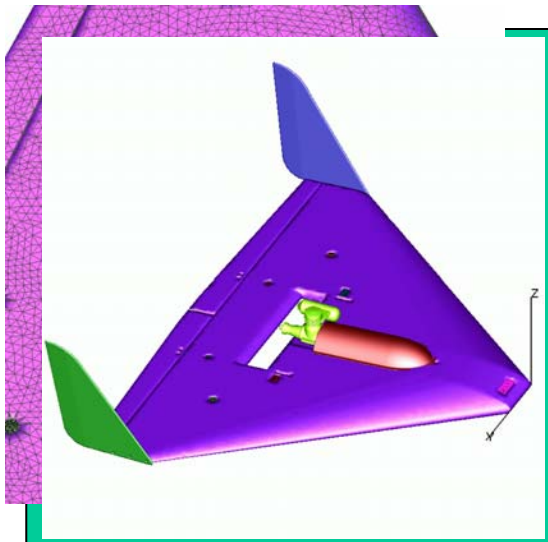

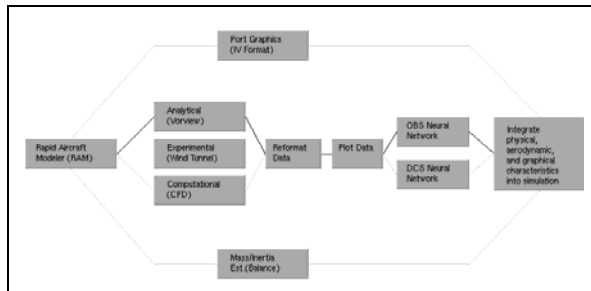

- Maintain safe distance from the **Lander** and ensure local stability.
- Point in the desired attitude and follow a trajectory to enable imaging of interesting Geological Picture.
- Optimize long-term and short-term goals, such as minimization of fuel (long-term) and avoid collision with the **Lander** (short-term)
- React to changing environments by adapting the control functionality

# Level 2 Architecture

# Concluding Remarks

- ✓ Intelligent control comes in many flavors
- ✓ Levels of Intelligent Control is one way of quantifying the roles of Intelligent control
- ✓ Intelligent control architectures allow for fast prototyping
- ✓ Intelligent control architectures can guarantee inner-loop stability
- ✓ For UAV application, intelligent control provides a robust way to accommodate any outer-loop architecture for planning, etc.
